(57) **ABSTRACT**

A video game system includes a video game machine, a memory medium and a controller. A CPU included in the video game machine detects a vibration generating condition that a player object comes into collision or contact with an enemy object or a stationary object. If the vibration generating condition is detected, the CPU drives a vibration source included in the controller, thereby generating vibration on the controller.

VIDEO GAME SYSTEM

BACKGROUND OF THE INVENTION

[0001] 1. Field of the invention

[0002] This invention relates to video game systems. More specifically, this invention relates to a novel video game system having a vibration source provided within a controller to supply operating signals to a video game machine, generating vibrations in response to game images.

[0003] 2. Description of the prior art

[0004] The conventional business-use video game machines involves so-called a bodily-sensible game machine already placed in practical use, which is adapted to cause vibration on a player's seat or tilt in the seat in order to enhance interest in a game further more.

[0005] Meanwhile, there is a controller, disclosed, e.g. in Japanese Utility Model Laying-Open No. S62-194389 laid open on Dec. 10, 1987, which has an electromagnet arranged within a joystick lever to cause vibration on the joystick lever due to the actuation of the electromagnet. It may be considered that such a game is available that vibration is transmitted to a player's hand by connecting a controller generative of vibration to a home-use video game machine.

[0006] In the prior art, however, there is no disclosure as to interrelations between the game images displayed on a display and vibration caused therefor. It is therefore difficult for such a prior art to utilize for a home-use video game system. Further, the above-mentioned bodily-sensible game machine is to generate vibration on the seat, and cannot be utilized for a home-use video game system without having such a seat.

SUMMARY OF THE INVENTION

[0007] Therefore, it is a primary object of this invention to provide a video game system which is capable of transmitting vibration to a player in a manner related to game images.

[0008] This invention is a video game system, having a video game machine and a controller, wherein the video game machine includes a processing means for generating game images displayed on a display depending upon an operating state of the controller and according to a game program memorized in the memory medium, the controller being used in a state of being gripped by a hand of a player, and comprising: a plurality of operating switches for designating a movement or motion of a player object; a vibration source for generating mechanical vibration; and a drive circuit for driving the vibration source in response to a command signal supplied from the video game machine; the memory medium comprising: a player object image generating program for generating an image of the player object that is varied in response to operation of at least one of the operating switches; an other object image generating program for generating an image of at least one other object that is present around the player object; a vibration generating condition detecting program for detecting a vibration generating condition based on a display state of the player object image and the other object image; and a vibration control program for generating data to control the vibration source in response to detection of the vibration generating condition

according to the vibration generating condition detecting program; and the processing means generating the game images according to the player object image generating program and the other object image generating program, and causing through the drive circuit the vibration source to generate, according to the vibration control program, mechanical vibration at timing synchronous with generation of frames on the display.

[0009] This invention is a video game system, having a video game machine and a controller for supplying an operating signal thereto, wherein the controller is used in a state of being gripped by a hand of a player, and comprises a plurality of operating switches for designating a movement or motion of a player object, a vibration source for generating mechanical vibration, and a drive circuit for driving the vibration source in response to a command signal supplied from the video game machine, the video machine, comprising: a player object image generating means for generating an image of the player object that is varied in response to operation of at least one of the operating switches; a vibration generating condition detecting means for detecting a vibration generating condition based on an operating state of the operating switches of the controller; and a vibration generating means for causing through the drive circuit the vibration source to generate mechanical vibration at timing synchronous with generation of frames on a display, in response to detection of the vibration generating condition by the vibration generating condition detecting means.

[0010] The vibration generating condition is detected depending upon a state of the player object image and other object images (e.g. whether they are in hitting or the like). If this condition is detected, the vibration source included in the controller is driven by the drive circuit.

[0011] Also, it is possible to generate vibration depending upon a state of the operating switches of the controller, regardless of a state of the player object and the other objects.

[0012] According to this invention, vibration can be generated by the vibration source of the controller depending upon a state of game images. Accordingly, game play is possible with further realism.

[0013] The above described objects and other objects, features, aspects and advantages of the present invention will become more apparent from the following detailed description of the present invention when taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0031] Referring to FIG. 1, a video game system in this embodiment includes a video game machine 10, a ROM cartridge 20 as one example of a memory medium, a display 30 connected to the video game machine 10, and a controller 40. The controller 40 is detachably mounted with a vibration cartridge 50.

[0032] The controller 40 is structured by a plurality of switches or buttons provided on the housing 41 formed graspable by both or one hand. Specifically, the controller 40 includes handles 41L, 41C, 41R downwardly extending respectively from a left end, a right end and a center of the housing 41, providing an operating area in an upper surface of the housing 41. In the operating area, there are provided an analog-inputtable joystick (hereinafter referred to as "analog joystick") 45 at a central lower portion thereof, a cross-shaped digital direction switch (hereinafter called "cross switch") 46 on the left side, and a plurality of button switches 47A, 47B, 47D, 47E and 47F on the right side.

[0033] The analog joystick 45 is used to input a moving direction and/or moving speed or moving amount of a player object (an object operable by a player through the controller 40) determined by the amount and direction of inclination of the joystick. The cross switch 46 is used to designate a moving direction of the player object, in place of the joystick 45. The button switches 47A and 47B are used to designate a motion of the player object. Button switches 47C-47D are used to switch over a visual point of a three-dimensional image camera or adjust speed or the like of the player object. A start switch 47S is provided nearly at a center of the operating area. This start switch 47S is operated when

starting a game. A switch 47Z is provided at a backside of the central handle 41C. This switch 47Z is utilized, for example, as a trigger switch in a shoot game. Switches 47L and 47R are provided on a side surface at upper left and right of the housing 41.

[0034] Incidentally, the above-stated button switches 47C-47F can also be used to control the moving speed (e.g. acceleration or deceleration) of the player object in a shoot or action game, besides for the purpose of switching the camera visual point. However, these switches 47A-47F, 47S, 47Z, 47L and 47R can be arbitrarily defined in their function depending upon a game program.

[0035] FIG. 2 is a block diagram of the video game system of the FIG. 1 embodiment. The video game machine 10 incorporates therein a central processing unit (hereinafter referred to as "CPU") 11 and a coprocessor (reality coprocessor: hereinafter referred to as "RCP") 12. The RCP 12 includes a bus control circuit 121 for controlling buses, a signal processor (reality signal processor; hereinafter referred to as "RSP") 122 for performing polygon coordinate transformation, shading treatment and so on, and a rendering processor (reality display processor; hereinafter referred to as "RDP") 46 for rasterizing polygon data into an image to be displayed and converting the same into a data form (dot data) memorable on a frame memory.

[0036] The RCP 12 is connected to a cartridge connector 13 for unloadably loading a ROM cartridge 20 having an external ROM 21 incorporated therein, a disc-drive connector 197 for detachably mounting a disc drive 29, and a RAM 14. Also, the RCP 12 is connected with DAC (Digital/Analog Converters) 15 and 16 for respectively outputting a sound signal and video signal to be processed by the CPU 11. Further, the RCP 12 is connected with a controller control circuit 17 to serially transfer operating data on one or a plurality of controllers 40 and/or data of the vibration cartridge 50.

[0037] The bus control circuit 121 included in the RCP 12 performs parallel/serial conversion on a command supplied in a parallel signal from the CPU via a bus, to thereby supply a serial signal to the controller control circuit 18. Also, the bus control circuit 121 converts a serial signal inputted from the controller control circuit 17 into a parallel signal, giving an output to the CPU 11 via the bus. The data representative of an operating state (operating signal or operating data) read out of the controller 40A-40D is processed by the CPU 11, and temporarily stored within a RAM 14, and so on. In other words, the RAM 15 includes a storage site for temporarily memorizing the data to be processed by the CPU 11, so that it is utilized for smoothly reading and writing data through the bus control circuit 121.

[0038] The sound DAC 15 is connected with a connector 195 provided at a rear face of the video game machine 10. The image DAC 16 is connected with a connector 196 provided at the rear face of the video game machine 10. The connector 195 is connected with a speaker 31 of a display 30, while the connector 196 is connected with a display 30 such as a TV receiver or CRT.

[0039] The controller control circuit 17 is connected with a controller connector provided at the front face of the video game machine 10. The connector 18 is disconnectably connected by a controller 40 through a connecting jack. The

connection of the controller **40** to the connector **18** places the controller in electrical connection to the video game machine **10**, thereby enabling transmission/reception or transfer of data therebetween.

[0040] The controller control circuit **17** is used to transmit and receive data in serial between the RCP **12** and the connector **18**. The controller control circuit **17** includes, as shown in FIG. 3, a data transfer control circuit **171**, a transmitting circuit **172**, a receiving circuit **173** and a RAM **174** for temporarily memorizing transmission and reception data. The data transfer control circuit **171** includes a parallel/serial converting circuit and a serial/parallel converting circuit in order to convert a data format during data transfer, and further performs write/read control on the RAM **174**. The serial/parallel converting circuit converts the serial data supplied from the RCP **12** into parallel data, supplying it to the RAM **174** or the transmitting circuit **172**. The parallel/serial converting circuit converts the parallel data supplied from the RAM **174** or the receiving circuit **173** into serial data, to supply it to the RCP **12**. The transmitting circuit **172** converts the command for reading signals from the controller **40** and the writing data (parallel data) to the vibration cartridge **50**, into serial data to be delivered to channels CH1-CH4 corresponding to the respective controllers **40**. The receiving circuit **173** receives, in serial data, operational state data of the controllers inputted through corresponding channels CH1-CH4 and data read from the vibration cartridge **50**, to convert them into parallel data to be delivered to the data transfer control circuit **171**. The data transfer control circuit **171** writes into the RAM **174** data transferred from the RCP **12**, data of the controller received by the receiving circuit **183**, or data read out of the RAM cartridge **50**, and reads data out of the RAM **174** based on a command from the RCP **12** so as to transfer it to the RCP **12**.

[0041] The RAM **174**, though not shown, includes memory sites for the respective channels CH1-CH4. Each of the memory sites is stored with a command for the channel, transmitting data and/or reception data.

[0042] FIG. 4 is a detailed circuit diagram of the controller **40** and the vibration cartridge **50**. The housing of the controller **40** incorporates an operating signal processing circuit **44**, etc. in order to detect an operating state of the joystick **45**, switches **46**, **47**, etc. and transfer the detected data to the controller control circuit **17**. The operating signal processing circuit **44** includes a receiving circuit **441**, a control circuit **442**, a switch signal detecting circuit **443**, a counter circuit **444**, a joyport control circuit **446**, a reset circuit **447** and a NOR gate **448**. The receiving circuit **441** converts a serial signal, such as a control signal transmitted from the controller control circuit **17** or writing data to the vibration cartridge **50**, into a parallel signal to supply it to the control circuit **442**. The control circuit **442** generates a reset signal to reset (0), through the NOR gate **448**, count values of an X-axis counter **444X** and a Y-axis counter **444Y** within the counter **444**, when the control signal transmitted from the controller control circuit **17** is a signal for resetting X, Y coordinates of the joystick **45**.

[0043] The joystick **45** includes X-axis and Y-axis photo-interrupters in order to decompose a lever inclination into X-axis and Y-axis components, generating pulses in number proportional to the inclination. The pulse signals are respectively supplied to the counter **444X** and the counter **444Y**.

The counter **444X** counts a number of pulses generated in response to an inclination amount when the joystick **45** is inclined in the X-axis direction. The counter **444Y** counts a number of pulses generated responsive to an inclination amount when the joystick **45** is inclined in the Y-axis direction. Accordingly, the resultant X-axis and Y-axis vector determined by the count values of the counters **444X** and **444Y** serves to determine a moving direction and a coordinate position of the player object or hero character or a cursor. Incidentally, the counter **444X** and the **444Y** are reset, when a reset signal is supplied from the reset signal generating circuit **447** upon turning on the power or a reset signal is supplied from the switch signal detecting circuit **443** by simultaneous depression of predetermined two switches.

[0044] The switch signal detecting circuit **443** responds to a switch-state output command supplied at an interval of a constant period (e.g. a $\frac{1}{30}$ second interval as a TV frame period) from the control circuit **442**, to read a signal varying depending upon a depression state of the cross switch **46** and the switches **47A-47Z**. The read signal is delivered to the control circuit **442**. The control circuit **442** responds to a read-out command signal of operational state data from the controller control circuit **17** to supply in a predetermined data format the operational state data on the switches **47A-47Z** and count values of the counters **444X** and **444Y** to the transmitting circuit **445**. The transmitting circuit **445** converts the parallel signal outputted from the control circuit **442** into a serial signal, and transfer it to the controller control circuit **17** via a converting circuit **43** and a signal line **42**. The control circuit **442** is connected with a joystick control circuit **446** via an address bus and a data bus as well as a port connector **46**. The joyport control circuit **446** performs data input/output (or transmission/reception) control according to a command from the CPU **11** when the vibration cartridge **50** is connected to the port connector **46**.

[0045] The vibration cartridge **50** is structured by connecting the RAM **51** to the address bus and data bus and connecting the RAM **51** with a battery **52**. The RAM **51** is a RAM having a capacity (e.g. 256 k bits), for example, of lower than a half of a maximum memory capacity accessible through the address bus. The RAM **51** is to store backup data in relation to a game, and keeps backup data by the application of electric power from the battery **52** even if the vibration cartridge **50** is withdrawn from the port connector **449**. This vibration cartridge **50** incorporates a vibration generating circuit **53** therein.

[0046] Now the vibration cartridge will be explained in detail with reference to FIG. 5. The vibration cartridge **50** includes a case **501** and a back lid **502** attached to the case **501**. The vibration cartridge **50**, formed by this case **501** and the back lid **502**, is dismountably mounted in an opening portion of the controller **40** shown in FIG. 1.

[0047] The case **501** has a substrate **503** accommodated therein. On the substrate **503** are mounted, besides the afore-mentioned RAM **51** and a backup battery **52**, a battery **504** and a driving circuit **505** that constitute the vibration generating circuit **53** of FIG. 4. Incidentally, the substrate **503** has a plurality of terminals **506** at an edge portion toward this so that the terminals **506** are to be connected to

a connector (not shown) formed at an opening portion of the above-stated controller 40. Through these terminals 506 are received data and addresses supplied from the CPU 11 (FIG. 2), that is, the controller control circuit 17 of the video game machine 10.

[0048] The back lid 502 is fixed with a vibration source 507 constituting the vibration generating circuit 53. In this embodiment, the vibration source 507 employs a motor to generate vibrations. However, it is of course possible to utilize, besides a motor, other devices, such as a solenoid, for generating vibration by the application of power. Incidentally, "FM16", "FM23", "FM25", "FM29" or "CM-5", etc. made by Tokyo Parts Industry Co., Ltd. are available as a vibration generating motor. Where using an "FM" motor, an eccentric member is attached to a rotary shaft built in a cylindrical case. When the rotary shaft is rotated, the eccentric member is rotated to cause vibration on the case. When a "CM" motor is used, an armature coil is eccentrically arranged. By rotating the armature, vibration is caused. Incidentally, if a solenoid is used, vibration occurs due to reciprocal movement of a magnetic core provided within the solenoid.

[0049] In any of the cases, the vibration source 507 structured as above is applied by power from the battery 504 and driven by the driving circuit 505, thereby causing vibration. The power consumed by the oscillation source 507 is comparatively great. Accordingly, in this embodiment the battery 504 was provided separately from the backup battery 52 (FIG. 4). Due to this, when the battery 504 is consumed, a battery lid removably fitted to the back lid 502 can be opened to allow the battery 504 to be exchanged with a new one. Note that the two batteries 52 and 504 may be a same one for common use.

[0050] Also, a power line may be included in a controller cable (not shown) so that power is supplied through the power line from the image processing apparatus main body or video game machine 10 via the terminals 506 to the vibration source 507. In such a case, it is needless to say that the capacity of the power line be appropriately determined in consideration of power required for the vibration source 507.

[0051] Further, in this embodiment, the vibration source 507 was mounted on the back lid 502 so that the vibration caused by the vibration source 507 is readily delivered to a player's hand, without attenuation. That is, the vibration caused by the vibration source 507 is transmitted through the back lid 502 to the opening portion of the controller 40 in contact with the back lid 502, thus vibrating the controller 40 itself. As a result, the vibration caused by the vibration source 507 is transmitted to the player's hand gripping the controller 40. It is therefore possible to provide the vibration source 507 at an arbitrary position within the case 501, provided that the vibration by the vibration source 507 is transmitted through the controller 40 to the player's hand.

[0052] Incidentally, this embodiment provided the vibration source 507 in the controller by mounting the vibration cartridge 50 on the controller 40. However, the vibration generating circuit 53 (FIG. 4), i.e. the vibration source 507, driving circuit 505, battery 504, etc. may be built in the housing of the controller 40 without using a vibration cartridge 50.

[0053] Now, the driving circuit 505 constituting the vibration generating circuit 53 will be explained in detail with

reference to FIG. 6. The driving circuit 505 includes a decoder comprising a NAND gate 510. This NAND gate 510 receives address data A2-A14 through an address bus, i.e. the terminals 506 (FIG. 5) from the CPU 11 (FIG. 2) of the video game machine 10. In the game machine system of this embodiment, when all the addresses A0-A15 are "1", that is, when the CPU 11 designates an address range FFFF, a vibration mode is established to output data from the CPU 11 to drive a vibration source 507. That is, if the CPU address FFFF is designated, the output of the decoder, i.e. NAND gate 510, becomes "0". This output of the NAND gate 510 is supplied to a NAND gate 511. Since the NAND gate 511 is further supplied with a write signal-WE and a chip enable signal CE from the CPU 11, the NAND gate 511 responds to the output of the NAND gate 510 and the signals-WE and CE, to supply a latch signal to a latch 512. Consequently, when the CPU 11 designates the FFFF address, i.e. in the vibration mode, the latch 512 latches CPU data D0 through the data bus or terminals 506. This CPU data D0 is outputted as "1" when vibration is to be caused by the vibration source 507, and "0" when no vibration is to be generated. The latch 512 has an output connected to a base of a drive transistor 514 through a resistor 513. When the output of the latch 512 is "1", the transistor 514 is turned on, whereas when the output is "0" the transistor is turned off. The turning-on of the transistor 514 causes a drive current to flow from the battery 504 to the vibration source 507 (vibration motor). Thus, vibration is generated by the drive source 507.

[0054] FIG. 7 is a memory map showing a memory space of the external ROM 21 incorporated in the ROM cartridge 20 (FIG. 1). The external ROM 21, for example, includes a plurality of memory areas (hereinafter referred to merely as "area") such as a program area 22, a character code area 23, an image data area 24 and a sound memory area 25, as shown in FIG. 5, thereby previously storing various program in a fixed manner.

[0055] The program area 22 is stored with programs required to process for game images, and game data and the like in accordance with a game content. Specifically, the program area 22 includes memory areas 12a-22p to previously store operating programs for the CPU 11 in a fixed manner. A main program area 22a is stored with a main routine processing program, for example, for a game shown in FIG. 9 stated later. A control pad data determining program area 22d is stored with a program for processing operational data on the controller 40. A write program area 22c is stored with a write program by which the CPU 11 causes the RCP 12 to perform writing into a frame memory and Z buffer. For example, the write program area 22c is stored with a program to write, into an image data area 201 (FIG. 8) of the RAM 14, chrominance data as image data based on texture data for a plurality of movable objects or background objects to be displayed in one background scene. A move program area 22d is stored with a control program by which the CPU 11 causes the RCP 12 to vary the position of a moving body in a three-dimensional space. A camera control program area 22e is stored with a camera control program that controls as to in which direction and/or position the movable objects including player object or the background objects are to be photographed in the three-dimensional space. A player object program area 22f is stored with a program that controls display of an object operated by the player. An enemy object program area 22g

is stored with a program that controls display of an enemy object to make attacking on the player object. A background program area **22h** is stored with a background creating program by which the CPU causes the RCP **12** to create a three-dimensional background scene.

[0056] The character code area **23** is an area to store a plurality of kinds of character codes, e.g. a plurality of kinds of character dot data corresponding to codes. The character code data stored in the character code area **23** is utilized to display an instructing text to the player in the process of a game.

[0057] An image data area **24** is stored with image data, such as coordinate data of a plurality of polygons for each of the background object and/or movable objects, and texture data, and also a display control program to display these objects stationary at a predetermined position or in a moving state.

[0058] A sound memory area **25** is stored with sound data, such as phrases for outputting in sound the above message, effect sounds, game musics, etc., in a manner appropriate for a scene.

[0059] Incidentally, the memory medium or external memory device may use various kinds of memory mediums, such as CD-ROMs or magnetic discs, in place of or in addition to the ROM cartridge **20**. In such a case, a disc drive **29** (FIG. 2) is provided in order to read or write, if required, various data (including program data and data for image presentation) for a game from or onto an optical or magnetic disc memory medium such as a CD-ROM or magnetic disc. The disc drive **29** reads data out of a magnetic disc or optical disc magnetically or optically memorizing program data similarly to the external ROM **21**, and transfer the same data to the RAM **14**.

[0060] FIG. 8 is a memory map showing a memory space of the RAM **14**. The RAM **14** includes an image data area **201** and a program area **202**. The image data area **201** includes, though not shown, a frame memory area for temporarily storing 1 frame of image data and a Z buffer area for storing the depth data on a dot basis in the frame memory area. The program data area **202** is an area for temporarily storing a program. The program data, allocated to the area (FIG. 7) of the ROM **21**, is temporarily memorized, as required, on the program data area **202** so that the CPU **11** and the RCP **12** (FIG. 2) can proceed with a game by accessing to the program area of the RAM **14**. Similarly, the image data area **201** is an area for temporarily memorizing, as required, the image data stored in the ROM **21**, which can be directly accessed by the CPU **11** or the RCP **12**. That is, the image data area **201** memorizes coordinate data and texture data of a plurality of polygons constituting stationary objects and/or movable objects stored, for game image display, in the external ROM **21**. Prior to image processing, one course or stages of data, for example, is transferred from the external ROM **21** to the image data area **201**.

[0061] A controller data memorizing area **141** temporarily memorizes operating state data representative of an operating state read from the controller **40**.

[0062] Also, a flag/register area **142** sets a flag as required or memorizes a variable or constant while the CPU **11** is executing a program. The flags that can be set in this

flag/register area **143** includes a vibration game flag **F1**, a hit flag **F2**, a preceding-frame flag **F3** and a vibration flag **F4**.

[0063] The vibration game flag **F1** is to represent as to whether a game now being played includes a scene that vibration is to be generated by the vibration source **507** of the vibration cartridge **50**. The vibration game flag **F1** is set at "1" when such a scene exists, and "0" for a case other than that case. The hit flag **F2** is set at "1" when two objects becomes collision or contact due to a hit determining routine (FIG. 11) stated later, and "0" for a case other than that case. The preceding-frame **F3** is to set whether the hit flag **F2** is set to "1" at a frame previous by 1 frame on the display **30**, that is, whether two objects came into collision or contact with each other at an immediately preceding frame. The preceding frame **F3** is set at "1" when a hit determination is made at the immediately preceding frame, and "0" for a case other than that case. The vibration flag **F4** is set at "1" when vibration is to be generated by the vibration source **507**, and "0" for a case other than that case.

[0064] A variable **n_add** is an increment value for each frame, to increase a count value **n** of a counter **CT** in a vibration generating condition detecting routine (FIG. 10) stated after, while a variable **n_add_m** is a value varied by the increment value **n_add**. The counter **CT** has a data size of 32 bits, so that it drives vibration source **507** (FIG. 5) to generate vibration when its count value **n** exceeds "255" as in a 256 (8-bit binary) counter. Variables **ax**, **ay** and **az** are respectively acceleration components in directions of an X-axis, Y-axis and Z-axis of the player object. Variables **fx**, **fy** and **fz** are values respectively multiplied of the acceleration components **ax**, **ay** and **az** by constants **accx**, **accy** and **accz**.

[0065] Incidentally, the variables **n_add** and **n_add_m** may be a constant. In the embodiment, the variable **n_add** is set at "255" or "150". Meanwhile, the variable **n_add_m** is set, for example, at "20" or "10".

[0066] FIG. 9 is a main flowchart for the video game system of this embodiment. If a power is turned on, the CPU, at a first step **S1**, sets the video game machine **10** into a predetermined initial state. For example, the CPU **11** transfers a start program, among the game programs stored in the program area **22** of the external ROM **21**, to the program area **202** of the RAM **14**, and sets each parameter at an initial value, thereafter sequentially executing steps of FIG. 9.

[0067] The operation of the main flowchart of FIG. 9 is executed, for example, every 1 frame ($\frac{1}{60}$ second) or every two or three frames, wherein steps **S2-S14** are repeatedly executed before the course is cleared. If the game becomes over without success of course clear, a game-over process is effected at a step **S15** following the step **S14**. If course clear is successfully done, the process returns from the step **S13** to the step **S1**.

[0068] That is, at the step **S1**, display is made for a game course screen and/or course choosing screen. However, where a game is started after turning on a power, a first course screen is displayed. If the first course is cleared, a next course is set.

[0069] Following the step **S1**, a controller process is effected at a step **S2**. In this process, it is detected whether any of the joystick **45**, the cross switch **46** and the switches **47A-47Z** of the controller **40** is operated or not. Detected

data (controller data) on this operating state is read in, and the controller data thus read is written into the controller data area 141 of the RAM 14.

[0070] At a step S3, a process for displaying the player object is performed. This process is basically to vary the position, direction, shape and location of the player object depending upon an operating state of the joystick 45 manipulated by the player and the presence or absence of attacks by an enemy. For example, polygon data to be varied is determined by calculation based on a program transferred from the memory area 22f (FIG. 7) of the external ROM 21, polygon data of the player object transferred from the memory area 24, and controller data, i.e. an operating state of the joystick 45. A plurality of polygons thus obtained are given colors due to a picture data.

[0071] At a step S4, a camera process is performed. For example, calculation is made for a visual point to the respective objects such that a visual line or field as viewed through a camera finder is in an angle at which the player designates by a joystick 45.

[0072] At a step S5, an enemy object process is performed. This process is effected based on the polygon data of an enemy object transferred from the memory area 22g and the memory area 24 (FIG. 2) and according to a program partly transferred. For example, an enemy object is determined in display position and/or shape by calculating the polygon data such that the enemy object moves to attack the player object or block against its advancing while judging movement of the player object, thereby displaying an enemy object image thus varied. Due to this, the enemy object will move such that it has a certain effect upon the player object.

[0073] At a step S6, a background (stationary) object process is performed. This process is to calculate a display position and shape of a stationary object based on a program partly transferred from the memory area 22h and polygon data of a stationary object transferred from the memory area 24 (FIG. 2).

[0074] At a step S7, the RSP 122 performs a rendering process. That is, the RCP 12 performs a conversion process (coordinate transformation process and frame memory rendering process), under control of the CPU 11, on image data for displaying a movable object and a stationary object based on the respective texture data for the movable object, such as an enemy object, the player object, etc. and the stationary object, such as a background, memorized in the image data area 201 of the RAM 14. Specifically, colors are put to a plurality of polygons for each of the movable objects and the stationary objects.

[0075] At a step S8, the CPU 11 performs a sound process based on sound data, such as of messages, musics, effect sounds, etc.

[0076] At a next step S9, the CPU 11 performs a vibration condition detecting process. That is, the RCP 12 at this step S9 executes a subroutine of FIG. 10, based on the image data of the player object and the enemy object or the stationary object or based on the operating data supplied from the controller 40, thereby detecting whether a condition under which vibration is to be generated by the vibration source 507 is established or not. Incidentally, a vibration condition detecting subroutine will be explained in detail later with reference to FIG. 10.

[0077] At a next step S10, the CPU 11 responds to a detection of a vibration generating condition by the step S9, to execute a subroutine shown in FIG. 12, thereby causing vibration by the vibration source 507. This step S10 will be also explained in detail with difference to FIG. 12.

[0078] At a step S10, the CPU 11 reads the image data memorized in the frame memory area of the RAM 14 as a result of the rendering process by the step S7. This causes the player object, the movable object, the stationary object, and the like to be displayed on a display screen of the display 30 (FIG. 1, FIG. 2).

[0079] At a step S12, the sound data that has been sound processed at the step S8 by the RCP 12 is read out to thereby output a sound, such as a music, effect sound conversation or the like.

[0080] It is determined at a step S13 whether the course is cleared or not (course clear detection). If the course is not cleared, it is then determined at a step S14 whether it is game-over or not. If it is not game-over, the process returns to the step S2, to repeat the steps S2-F14 until a condition of game-over is detected. If detecting a game-over condition that a number of mistakes permitted for a player reaches a predetermined number of times or the life of the player object is consumed by a predetermined amount, then a game-over process is carried out at a succeeding step S15 to choose game continuation, backup data saving, or the like.

[0081] Incidentally, if the condition to clear the course is detected (e.g. defeating a boss) at the step S13, the process returns to the step S1 after course-clear processing.

[0082] Referring to FIG. 10, at a first step S101 of a vibration generating condition detecting subroutine, the CPU 11 determines whether or not the player object hits (collides or contacts) against an influencing object or obstacle (other movable objects, stationary objects such as ground, sea surface, wall, enemy objects, attacking objects, etc.). This hit detection is executed according to a subroutine of FIG. 11.

[0083] At a step S201 in FIG. 11, the CPU 11 determines whether $ABS (OBJ2x - OBJ1x) \leq OBJ1r$ is satisfied or not. That is, whether two objects are hit against each other on an X-coordinate system or not. OBJ1 is an object to be hit-determined, which in this embodiment is the player object. OBJ2 is an object moving toward OBJ1, which in this embodiment a fellow object, an enemy object, a stationary object and an attacking object launched by the enemy object. OBJ1x is an X-coordinate value of OBJ1, while OBJ2x is an X-coordinate value of OBJ2. OBJ1x and OBJ2x may be on a game space coordinate or player coordinate, provided that they are an X-coordinate value of a same coordinate system. ABS () represents an absolute value of a numeral within (). OBJ1r is a value representative of a half length of a side of a cube when OBJ1 is considered as a cube. In other words, OBJ1r is a value indicating a hit range for OBJ1. If $ABS (OBJ2x - OBJ1x) \leq OBJ1r$ is satisfied, the process proceeds to a step S202.

[0084] At a step S202, the CPU 11 determines whether $ABS (OBJ2y - OBJ1y) \leq OBJ1r$ is satisfied or not, that is, whether there is hit between two objects on a Y-coordinate system or not. OBJ1y is a Y-coordinate value of OBJ1, while OBJ2y is a Y-coordinate value of OBJ2. OBJ1y and OBJ2y may be on a game space coordinate or player coordinate,

provided that they are in a Y-coordinate value on a same coordinate system. If $ABS(OBJ2y - OBJ1y) \leq OBJ1r$ is fulfilled, the process advances to a step **S203**.

[**0085**] At the step **S203**, the CPU **11** determines whether $ABS(OBJ2z - OBJ1z) \leq OBJ1r$ stands or not, that is, whether there is a hit between two objects on the Z coordinate system or not. $OBJ1z$ is a Z-coordinate value of $OBJ1$, while $OBJ2z$ is a Z-coordinate value of $OBJ2$. $OBJ1z$ and $OBJ2z$ may be on a game space coordinate or player coordinate, provided that they are in a Z-coordinate value on a same coordinate system. If $ABS(OBJ2z - OBJ1z) \leq OBJ1r$ is satisfied, the process proceeds to a step **S204**.

[**0086**] At the step **S204**, the CPU **11** determines that there is a hit between $OBJ2$ and $OBJ1$, and sets a hit flag **F2** in the flag area **142** of the RAM **14** to "1".

[**0087**] On the other hand, if $ABS(OBJ2x - OBJ1x) \leq OBJ1r$ is not satisfied at the step **S201**, the process returns to a former routine. If $ABS(OBJ2y - OBJ1y) \leq OBJ1r$ is not profiled at the step **S202**, the process returns to the former routine. If $ABS(OBJ2z - OBJ1z) \leq OBJ1r$ is not satisfied at the step **S203**, the process returns to the former routine.

[**0088**] At the step **S101** in **FIG. 10**, if it is detected that the player object is not hit by another object, that is, if "NO" is determined at the step **S101**, the CPU **11** at a next step **S102** determines whether the player manipulates the controller **40** to start acceleration of the player object or not. For example, the acceleration start is effected by depressing an A button **47a** (**FIG. 1**), where the player object is a "jet ski" in a "wave race". Also, if the player object is "Mario", the acceleration start is by inclining the joystick **45** (**FIG. 1**) frontward. Accordingly, the CPU **11** at this step **S102** makes reference to the data in the controller data area **141** of the RAM **14**, and determines whether there is an operation of the A button **47a** or joystick **45** or not.

[**0089**] At the step **S102**, if "NO" is determine, the CPU **11** at a next step **S103** determines whether the player object ("jet ski" in the "wave race" in this embodiment) is in contact with a water surface or not. At the step **S103**, the hit detecting subroutine of **FIG. 11** is utilized in order to determine whether the player object ("jet ski") is in contact with the water surface or not.

[**0090**] In the vibration generating condition detecting subroutine shown in **FIG. 10**, detection is made for any of the three vibration generating conditions, i.e. any of the steps **S101**, **S102**, and **S103**, as explained above. If "NO" is determined at any of the steps **S101**, **S102** and **S103**, that is, if no vibration generating condition is detected, the CPU **11** resets, at a step **S104** in **FIG. 10**, the register value n_add of the flag/register area **142** of the RAM **14** to "0". At same time, the CPU **11** at next step **S105** clear off the preceding frame flag **F3** of the flag/register area **142** to "0". That is, the count value n of the counter **CT** is added by "0" for each frame, in order to set the increment value n_add of the counter **CT** at "0". In other words, if "NO" is determined at all the steps **S101**, **S102** and **S103**, the counter **CT** is not incremented at all. As will be stated later, if the count value of the counter **CT** exceeds, for example, "255", vibration will occur. Accordingly, in the above case no vibration is generated by the vibration source **507**.

[**0091**] Incidentally, since "NO" is determined at the above-mentioned step **S101**, the preceding-frame flag **F3** is reset at the step **S105**.

[**0092**] If "YES" is determined at any of the steps **S101**, **S102** and **S103**, a vibration generating condition is established and a vibration generating process is effected according to the corresponding vibration generating condition.

[**0093**] That is, if it is determined, at the step **S101**, that the player object is hit against another object, steps **S106** to **S110** are executed to generate intense vibration from the vibration source **507**. Meanwhile, an acceleration start is detected at the step **S102**, weak vibration is generated by steps **S111** to **S113**. If the player object (e.g. "jet ski") is in contact with a water surface is detected at the step **S103**, steps **S114** to **S117** are executed to generate weak vibration representing a state that the "jet ski" moves bounding on waves.

[**0094**] If "YES" is determined at the above-mentioned step **S101**, that is, if the player object comes into collision or contact with another object is determined, the CPU **11** determines whether the preceding-frame flag **F3** is at "0" or not. That is, at this step **S106** it is determined whether the player object collided against another object also at the preceding frame or not. If at the step **S106** "YES" is determined, that is, if it is determined there was no collision or contact of the player object at the preceding frame but there is detection at a current frame of collision or contact of the player object with another object, the CPU **11** at a next step **S107** sets the increment value n_add of the flag/register area **142** of the RAM **14**, for example, to "255" in order to generate intense vibration.

[**0095**] That is, where the player object comes into collision or contact with an enemy object as shown in **FIG. 13**, or where the player object crashes into or contacts an enemy object or stationary object as shown in **FIG. 14**, a greater increment value n_add is set at a step **S107** in order to cause intense vibration.

[**0096**] Then the CPU **11** at a step **S108** sets a variation value n_add_m of the increment value n_add at "20". When there is collision or contact with another object, the increment value n_add is set to "255" at the step **S107** and the variation value n_add_m is set to "20" at the step **S108** in order to generate intense vibration. If the variation value n_add_m is great in value, the increment value n_add becomes "0" in a brief time, while if the variation value n_add_m is small, it takes a long time for the increment value n_add to reach "0". Therefore, when the variation value n_add_m is great, the vibration due to the vibration source **507** continues for a long time. At a step **S109** following the step **S108**, the CPU **11** sets the preceding-frame flag **F3** to "1". That is, since at the current frame the player object is detected of hit, the previous frame flag **F3** is set to "1" at this time point.

[**0097**] Incidentally, if "NO" is detected at the above-mentioned step **S106**, that is, if the preceding-frame flag **F3** is "1", that is, if there is also a detection of collision or contact of the player object at the preceding frame, the increment value n_add is reset to "0" at a step **S110**. That is, when the player object comes into contact or collision with another object also at the preceding frame, the increment value n_add is rendered "0" at the step **S110** in order to prevent vibration from continuously occurring.

[**0098**] At the step **S102**, if an acceleration start of the player object is detected, the CPU **11** sets the increment

value n_add , for example, to “150” at a next step S111 to generate weak vibration. That is, when an acceleration of the player object is started, the increment value n_add of the counter CT is set to “150” smaller than the value of the step S107 in order to generate comparatively small vibration differently from the case of the above-stated hit detection. The CPU 11 then sets the variation value n_add_m to “10” at a step S112. At a step S113, the preceding-frame flag F3 is rendered “0”. That is, this step S113 is a step to be executed when “NO” is determined at the above-mentioned step S101, and accordingly the preceding-frame flag F3 is rendered “0” in a manner different from that of the above step S109.

[0099] Further, if it is detected at the step S103 that the player object, i.e. “jet ski” in this embodiment, is in contact with a water surface, calculations are made for multiplying values f_x , f_y and f_z at a next step S114. The CPU 11 at a step S115 calculates a square root (decimal fraction truncated) of “ $f_x \times f_x + f_y \times f_y + f_z \times f_z$ ” as an increment value n_add of the counter CT. That is, at these steps S114 and S115, acceleration components a_x , a_y and a_z of the player object in the respective X-axis direction, Y-axis direction and Z-axis direction are determined to determine values f_x , f_y and f_z respectively proportional to the acceleration components. An increment value n_add in a range of “0”-“255” is calculated, depending upon these proportional values and multiplying values. At a step S116, the variation value n_add_m of the increment value n_add is set to, for example, “10”. That is, where the player object “jet ski” is in contact with the water surface, the variation value n_add_m is set at a relatively small value “10” in order to give impact for a comparatively long time. In also this case, since “NO” is determined at the above step S101, the preceding-frame flag F3 is rendered “0” at a succeeding step S117.

[0100] At a first step S120 in FIG. 12 showing a vibration generating subroutine, the CPU 11 determines whether the vibration game flag F1 in the flag/register area 142 of the RAM 14 is at “1” or not, that is, whether a game now being played is a game involving vibration or not. If “YES” is determined at this step S120, the CPU 11 makes reference to the controller data area 141 of the RAM 14, and determines whether a vibration cartridge 50 (FIG. 1, FIG. 4) is loaded on the controller 40 or not. If this game is a game with vibration and a vibration cartridge 50 is loaded on the controller 40, the CPU 11 determines at a next step S122 whether or not vibration has to be forcibly stopped despite a vibration generating condition is established, that is, whether vibration is reset or not.

[0101] If “NO” is determined at this step S122, the CPU 11 renders the count value n of the counter CT as “ $n+n_add$ ” at a next step S123. That is, the count value n of the counter CT is increased according to an increment value n_add .

[0102] At a next step S124, the increment value n_add is modified according to a variation value n_add_m . That is, the increment value n_add is subtracted by the variation value n_add_m , at this step S124, at every 1 frame of the display 30. Accordingly, the count value n of the counter CT has an increment value decreasing with progress of frames, and the count value n finally does not increase. In other words, the vibration due to the vibration source 507 is initially large (intense) and gradually decreases (weakens) to ultimate no vibration.

[0103] At a step S125, it is determined whether the count value n of the counter CT exceeds “255” or not. If “YES” is determined at this step S125, the count value of the counter CT is rendered “ $n-256$ ”. That is, if it is determined at the step S125 that the count value n of the counter CT exceeds “255”, the count value n is subtracted by “256” at a next step S126. At a step S127, the CPU 11 sets the vibration flag F4 at “1”. Since the count value n of the counter CT exceeds “255” is detected at the above step S125, the vibration flag F4 at this step S127 is set at “1”.

[0104] At a next step S128, it is determined whether the vibration flag F4 is at “1” or not. Since vibration is generated by setting the vibration flag F4 at “1” at the above step S127, the CPU 11 at a next step S129 outputs “1” to all the addresses A2-A14 except for an address A15, and outputs a write signal and a chip enable signal. Accordingly, at this step S129 a recorder or NAND gate 511 (FIG. 6) has an output signal, and the latch 512 latches data bit D0 of the CPU 11. Since at the step S129 vibration has to be generated by the vibration source 507, the data bit D0 of the CPU 11 is outputted as “1”. Accordingly, “1” is latched by the latch 512 (FIG. 6). In response thereto, the transistor 514 is turned on to supply power from the battery 504 to the vibration source or vibrating motor 507, thereby causing vibration in the vibration source 107 or vibration cartridge 50, i.e. on the controller 40.

[0105] Incidentally, if “NO” is determined at the step S125, the vibration flag F4 is reset at “0” at a step S130. That is, when the count value n of the counter CT does not exceed “255”, the vibration flag F4 is kept in a reset state.

[0106] At the step S127, when the vibration flag F4 is not at “1”, that is, when the vibration flag F4 is at “0”, the CPU 11 outputs “0” to the data bit “D0” at a step S131, in order to stop the vibration. Consequently, “0” is latched by the latch 512, and the transistor 514 is turned off. Accordingly, the vibration source 507 has no current, and no vibration is generated by the vibration source 507.

[0107] For example, if the player object comes into collision or contact with an enemy object or stationary object (FIG. 13, FIG. 14), “255” is set as an increment value n_add of the count value n of the counter CT at the step S107, and “20” is set as a variation value n_add_m at the step S108. The count value n of the counter CT exceeds “255” over consecutive 4 frames excepting the first frame as shown in Table 1 and FIG. 15. Therefore, the vibration source 507 is continuously driven over the consecutive 4 frames, and thereafter the count value n exceeds “255” every two frames. The vibration source 507 generates a comparatively intense vibration driven every two frames.

TABLE 1

INTENSE VIBRATION EXAMPLE				
FRAME	n	n_add	n_add_m	VIBRATION SIGNAL
1	255	255	20	0
2	234	235	20	1
3	193	215	20	1
4	132	195	20	1
5	51	175	20	1
6	206	155	20	0
7	85	135	20	1

TABLE 1-continued

INTENSE VIBRATION EXAMPLE				
FRAME	n	n_add	n_add_m	VIBRATION SIGNAL
8	200	115	20	0
9	39	95	20	1
10	114	75	20	0
11	169	55	20	0
12	204	35	20	0
13	219	15	20	0
14	219	0	20	0
15	219	0	20	0
16	219	0	20	0
17	219	0	20	0
18	219	0	20	0
19	219	0	20	0
20	219	0	20	0

[0108] However, when starting an acceleration for the player object, comparatively weak vibration is generated. Accordingly, “150” is set as an increment value n_add at a step S111, and “10” is set as a variation value n_add_m at a step S112. Consequently, in this case the count value n exceeds “255” every two frames as shown in Table 2 (FIG. 16) so that the vibration source 507 is driven every two frames and the following 2 frames are suspended of vibration. At a next 1 frame the vibration source 507 is driven, and thereafter the vibration is suspended for 2 frames.

TABLE 2

WEAK VIBRATION EXAMPLE				
FRAME	n	n_add	n_add_m	VIBRATION SIGNAL
1	150	150	10	0
2	34	140	10	1
3	164	130	10	0
4	28	120	10	1
5	138	110	10	0
6	238	100	10	0
7	72	90	10	1
8	152	80	10	0
9	222	70	10	0
10	26	60	10	1
11	76	50	10	0
12	116	40	10	0
13	146	30	10	0

15	176	10	10	0
16	176	0	10	0
17	176	0	10	0
18	176	0	10	0
19	176	0	10	0
20	176	0	10	0

[0109] That is, where generating intense vibration, the vibration source 507 is continuously driven over several frames and then the vibration is gradually decreased as if driven every 2 frames. When weak vibration is to be generated, the driving source 507 is driven every 2 frames and then the vibration is gradually decreased in a manner driven every 3 frames. However, it is needless to say that the increment value n_add or the variation value n_add_m, that is, the vibration generating pattern as above, can be set in an arbitrary manner.

[0110] Incidentally, under a third vibration generating condition, i.e. where the player object (“jet ski”) is in contact with a water surface, the increment value n_add is set as a function of acceleration of the player object, generating intense or weak vibration depending upon the acceleration.

[0111] Incidentally, in the above embodiment the count value n of the counter CT is varied according to an increment value n_add or an variation value n_add_m, by executing the flowchart of FIG. 12, in order to generate intense or weak vibration as shown in FIG. 15 or FIG. 16. When the count value n exceeds “255”, the vibration flag F4 is set to “1” to drive the vibration source 507. That is, in the above embodiment whether to generate vibration by the vibration source 507 is determined by calculation in a real time manner.

[0112] Contrary to this, intense and weak vibration pattern data, read out of the program area 22a of the external ROM 21, may be respectively memorized on the flag/register area 142 of the RAM 14, as shown, for example, in FIG. 17. By selectively reading out these vibration pattern data, the vibration source 507 may be controlled based on these pattern data. It can be considered that the intense vibration pattern data uses a vibration signal “0111101010000000” in a frame sequence of frames 1-16 in the afore-said Table 1. Meanwhile, the weak vibration pattern data may use a vibration signal “0101001001000000” in a frame sequence of frames 1-16 in the afore-mentioned Table 2. Incidentally, medium vibration pattern data may be memorized as required.

[0113] For example, when the player object is detected of its collision or contact at the step S101 in FIG. 10, if intense vibration pattern data is read out, the vibration source 507 is not driven by a first frame. However, the vibration source 507 is continuously driven over the following 4 frames, and then at every 2 frames, thereafter being ceased of drive. For example, when an acceleration start is detected at the step S102 in FIG. 10 or a contact with a water surface is detected at the step S103, weak vibration pattern data is read out. Consequently, the vibration source 507 is driven at every 2 frames during the first 4 frames, and then driven at every 3 frames, thereafter being ceased of drive.

[0114] In the above embodiment, when the player object is hit by another object or the like, vibration is generated by the vibration source 507 of the vibration cartridge 50 loaded on the controller 40. Vibration may be visually given to game images in timing related to this vibration. In such a case, the game-image vibration on the display 30 can be perceived with higher rapidity than the mechanical vibration caused by the vibration cartridge 50 of the controller 40. Accordingly, mechanical vibration may be generated by the vibration cartridge 50 at the step S10 in FIG. 9, and thereafter vibration is visually given to game images with a delay of 1 or 2 frames or more at the step S4 or S7 in FIG. 9.

[0115] For example, when it is detected at the step S101 of FIG. 10 that the player object comes into contact or collision against another object, since intense vibration is generated on a game images, the display 30 is vibrated at the entire screen. In this case, the visual coordinate for a camera stated before may be varied bit by bit during the camera process of the step S4 in FIG. 9.

[0116] When a condition of generating weak vibration is detected at the step S102 or S103 in FIG. 10, weak vibration

is generated on the game image. The player object image only is given vibration that is displayed on the display **30**. In such a case, a plurality of polygon sets, constituting the player object, may be varied in a center coordinate position bit by bit in the rendering process at the step **S7** in **FIG. 9**.

[**0117**] Incidentally, whether to give vibration to a game image may be determined by a condition whether “**F4=1**” is detected at the step **S128** in **FIG. 12**. That is, when the vibration flag **F4** is at “1”, vibration is given to the game image, while when the flag is at “0”, no vibration is generated in the game image.

[**0118**] Although the present invention has been described and illustrated in detail, it is clearly understood that the same is by way of illustration and example only and is not to be taken by way of limitation, the spirit and scope of the present invention being limited only by the terms of the appended claims.

What is claimed is:

1. A computer readable medium for use with a video game system comprising a video game machine, a hand-held controller connected to said video game machine and operable by a player to generate video game inputs, and a vibration source arranged to vibrate a housing of said hand-held controller, said computer readable medium having stored thereon instructions adapted to be executed by said video game machine, the instructions which, when executed, define a series of steps comprising:

detecting vibration generating conditions;

controlling a counter in accordance with the detected vibration generating conditions; and

generating vibration control data for controlling said vibration source based on a count of said counter.

2. The computer readable medium according to claim 1, wherein collisions between game objects are detected as vibration generating conditions.

3. The computer readable medium according to claim 1, wherein collisions between game objects in three-dimensional space are detected as vibration generating conditions.

4. The computer readable medium according to claim 1, wherein accelerations of game objects are detected as vibration generating conditions.

5. The computer readable medium according to claim 1, wherein vibration control data for driving said vibration source is generated when the count of said counter exceeds a predetermined count value.

6. The computer readable medium according to claim 1, wherein a count loaded into said counter and an increment value for the count of said counter are determined in accordance with the detected vibration generating conditions.

7. The computer readable medium according to claim 6, wherein a variation value of the increment value is also determined in accordance with the detected vibration generating conditions.

8. The computer readable medium according to claim 1, comprising an optical disc.

9. The computer readable medium according to claim 1, comprising a magnetic disc.

10. The computer readable medium according to claim 1, comprising a ROM cartridge.

11. A computer readable medium for use with a video game system comprising a video game machine, a hand-held controller connected to said video game machine and operable by a player to generate video game inputs, and a vibration source arranged to vibrate a housing of said hand-held controller, said computer readable medium having stored thereon:

vibration patterns each of which determines the on/off state of said vibration source for each frame of a sequence of frames; and

instructions adapted to be executed by said video game machine, the instructions which, when executed, define a series of steps comprising:

detecting vibration generating conditions; and

selecting the vibration patterns to control said vibration source in accordance with the detected vibration generating conditions.

12. The computer readable medium according to claim 11, wherein collisions between game objects are detected as vibration generating conditions.

13. The computer readable medium according to claim 12, wherein collisions between game objects in three-dimensional space are detected as vibration generating conditions.

14. The computer readable medium according to claim 11, wherein accelerations of game objects are detected as vibration generating conditions.

15. The computer readable medium according to claim 11, comprising an optical disc.

16. The computer readable medium according to claim 11, comprising a magnetic disc.

17. The computer readable medium according to claim 11, comprising a ROM cartridge.

18. The computer readable medium according to claim 11, wherein the vibration patterns include weak, medium and intense vibration patterns.
